

Extension of the entropy viscosity method to the
multi-D 7-equation two-phase flow model.
I do not know if we should have 'multi-D' in the title
since we will only present 1-D results

Abstract

blabla

Key words: two-phase flow model, with variable area, entropy viscosity method, stabilization method, low Mach regime, shocks.

1. Introduction

- a few lines about the need for accurately resolving two-phase flows
- background on the different two-phase flow models: 5, 6 and 7-equation two-phase flow models
- then, focus on the different types of 7-equation two-phase flow models: they mostly differ because of the closure relaxations used
- discuss the different numerical solvers developed for the 7-equation two-phase flow model: HLL, HLLC, and approximated Riemann solvers accounting for the source terms
- emphasize the fact that the above numerical solvers only works on discontinuous schemes
- then, introduce the entropy viscosity method and details the organization of the paper

14 2. The seven-equation two-phase flow model

The seven-equation two-phase flow model presented in this paper is obtained by assuming that each phase obeys the single-phase Euler equations (with phase-exchange terms) and by integrating over a control volume after multiplication by a phase characteristic function. The detailed derivation can be found in [1]. In this section, the governing multi-dimensional equations are recalled for a phase k in interaction with a phase j . Each phase obeys the following mass, momentum and energy balance equations, supplemented by a non-conservative equation for the void fraction:

$$\frac{\partial \alpha_k A}{\partial t} + A \mathbf{u}_{int} \cdot \nabla \alpha_k = A \mu_P (P_k - P_j) - \frac{\Gamma A_{int} A}{\rho_{int}} \quad (1a)$$

$$\frac{\partial (\alpha \rho)_k A}{\partial t} + \nabla \cdot (\alpha \rho \mathbf{u} A)_k = -\Gamma A_{int} A \quad (1b)$$

$$\begin{aligned} \frac{\partial (\alpha \rho \mathbf{u})_k A}{\partial t} + \nabla \cdot [\alpha_k A (\rho \mathbf{u} \otimes \mathbf{u} + P \mathbb{I})_k] &= P_{int} A \nabla \alpha_k + P_k \alpha_k \nabla A \\ &+ A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) - \Gamma A_{int} \mathbf{u}_{int} A \end{aligned} \quad (1c)$$

$$\begin{aligned} \frac{\partial (\alpha \rho E)_k A}{\partial t} + \nabla \cdot [\alpha_k \mathbf{u}_k A (\rho E + P)_k] &= P_{int} A \mathbf{u}_{int} \cdot \nabla \alpha_k - \bar{P}_{int} A \mu_P (P_k - P_j) \\ &+ A \lambda_u \bar{\mathbf{u}}_{int} \cdot (\mathbf{u}_j - \mathbf{u}_k) + \Gamma A_{int} \left(\frac{P_{int}}{\rho_{int}} - H_{k,int} \right) A \end{aligned} \quad (1d)$$

where α_k , ρ_k , \mathbf{u}_k and E_k denote the volume fraction, the density, the velocity vector and the total specific energy of phase k , respectively. The phasic pressure P_k is computed from an equation of state. The cross section of the geometry is denoted by A and is only spatially dependent. The interfacial pressure and velocity and their corresponding average values are denoted by P_{int} , \mathbf{u}_{int} , \bar{P}_{int} and $\bar{\mathbf{u}}_{int}$, respectively; they are defined in Eq. (2)

$$P_{int} = \bar{P}_{int} + \frac{Z_k Z_j}{Z_k + Z_j} \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} \cdot (\mathbf{u}_j - \mathbf{u}_k) \quad (2a)$$

$$\bar{P}_{int} = \frac{Z_j P_k + Z_k P_j}{Z_k + Z_j} \quad (2b)$$

$$\mathbf{u}_{int} = \bar{\mathbf{u}}_{int} + \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} \frac{P_j - P_k}{Z_k + Z_j} \quad (2c)$$

$$\bar{\mathbf{u}}_{int} = \frac{Z_k \mathbf{u}_k + Z_j \mathbf{u}_j}{Z_k + Z_j}. \quad (2d)$$

The interfacial specific total enthalpy of phase k , $H_{k,int}$, is defined as $H_{k,int} = h_{k,int} + 0.5 \|\mathbf{u}_{int}\|^2$, where $h_{k,int}$ is the phasic specific enthalpy evaluated at the

interface conditions (P_{int} and $T_{int} = T_{sat}(\bar{P}_{int})$). Following [1], the pressure and velocity relaxation coefficients, μ_P and λ_u respectively, are function of the acoustic impedance $Z_k = \rho_k c_k$ and the specific interfacial area A_{int} as shown in Eq. (3).

$$\lambda_u = \frac{1}{2} \mu_P Z_k Z_j \quad (3a)$$

$$\mu_P = \frac{A_{int}}{Z_k + Z_j} \quad (3b)$$

15 The specific interfacial area (i.e., the interfacial surface area per unit volume of
16 a two-phase mixture), A_{int} , is typically dependent upon flow regime conditions
17 and can be provided as a correlation. In [1], A_{int} is chosen to be a function of
18 the liquid volume fraction:

$$A_{int} = A_{int}^{max} \left[6.75 (1 - \alpha_{liq})^2 \alpha_{liq} \right], \quad (4)$$

with $A_{int}^{max} = 5100 \text{ m}^2/\text{m}^3$. With such definition, the interfacial area is zero in the limits $\alpha_k = 0$ and $\alpha_k = 1$. Lastly, Γ is the net mass transfer rate per unit interfacial area from phase j to phase k . Its expression, given in Eq. (5), is obtained by considering a vaporization/condensation process that is dominated by heat diffusion at the interface [1, 2]:

$$\Gamma = \Gamma_j = \frac{h_{T,k} (T_k - T_{int}) + h_{T,j} (T_j - T_{int})}{L_v (T_{int})}, \quad (5)$$

19 where $L_v (T_{int}) = h_{j,int} - h_{k,int}$ represents the latent heat of vaporization. The
20 interface temperature is determined by the saturation constraint $T_{int} = T_{sat}(P)$
21 with the appropriate pressure $P = \bar{P}_{int}$ defined previously. The interfacial heat
22 transfer coefficients for phases k and j are denoted by $h_{T,k}$ and $h_{T,j}$, respectively,
23 and computed from correlations [1].

The set of equations obeyed by phase j are simply obtained by substituting k by j and j by k in Eq. (1), keeping the same definition of the interfacial variables and noting that $\Gamma_j = -\Gamma_k$. In the case of two-phase flows, the equation for the volume fraction of phase j is simply replaced by the algebraic relation

$$\alpha_j = 1 - \alpha_k,$$

24 which reduces the number of partial differential equations from eight to seven
25 and yields the seven-equation two-phase flow model.

Properties of the seven-equation model are discussed next. A set of seven waves is present in such a model: two acoustic waves, a contact wave for each phase and by a volume fraction wave propagating at the interfacial velocity \mathbf{u}_{int} . Considering a spatial domain of dimension \mathbb{D} , the corresponding eigenvalues are

the following for each phase k :

$$\begin{aligned}
\lambda_1 &= \mathbf{u}_{int} \cdot \bar{\mathbf{n}} \\
\lambda_{2,k} &= \mathbf{u}_k \cdot \bar{\mathbf{n}} - c_k \\
\lambda_{3,k} &= \mathbf{u}_k \cdot \bar{\mathbf{n}} + c_k \\
\lambda_{d+3,k} &= \mathbf{u}_k \cdot \bar{\mathbf{n}} \text{ for } d = 1 \dots \mathbb{D},
\end{aligned} \tag{6}$$

where $\bar{\mathbf{n}}$ is a unit vector pointing to a given direction. The eigenvalues given in Eq. (6) are unconditionally real (as long as the chosen equation of state yields a real sound speed). Having real eigenvalues is a valuable property for the development of numerical methods since the system is hyperbolic and well-posed. To relax the seven-equation model to the ill-posed classical six-equation model, only the pressures should be relaxed toward a single pressure for both phases. This is accomplished by letting the pressure relaxation coefficient μ_P be very large, i.e., letting it approach infinity. But if the pressure relaxation coefficient goes to infinity, so does the velocity relaxation coefficient. This further relaxes the seven-equation model not to the classical six-equation model but to the mechanical equilibrium five-equation model of Kapila [3]. This reduced five-equation model is also hyperbolic and well-posed. Numerically, the mechanical relaxation coefficients μ_P (pressure) and λ_u (velocity) can be relaxed independently to yield solutions to useful, reduced models. However, It is noted that relaxation of pressure only by making μ_P large without relaxing velocity will indeed give ill-posed and unstable numerical solutions, just as the classical six-equation two-phase model does, with sufficiently fine spatial resolution, as confirmed in [1, 4].

For each phase k , an entropy equation can be derived and its sign proved positive when accounting only for the pressure and velocity relaxation terms (all of the terms proportional to the net mass transfer term Γ are removed). The entropy function for a phase k is denoted by s_k and a function of density ρ_k and internal energy e_k . The derivation is detailed in Appendix A and only the final result is recalled here:

$$\begin{aligned}
(s_e)_k^{-1} \alpha_k \rho_k A \frac{Ds_k}{Dt} &= \mu_P \frac{Z_k}{Z_k + Z_j} (P_j - P_k)^2 + \lambda_u \frac{Z_j}{Z_k + Z_j} (\mathbf{u}_j - \mathbf{u}_k)^2 \\
&\quad \frac{Z_k}{(Z_k + Z_j)^2} \left[Z_j (\mathbf{u}_j - \mathbf{u}_k) + \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} (P_k - P_j) \right]^2, \tag{7}
\end{aligned}$$

where $\frac{D(\cdot)}{Dt} = \partial_t(\cdot) + \mathbf{u} \cdot \nabla(\cdot)$ is the material derivative. The partial derivative of the entropy function s_k with respect to the internal energy e_k , $(s_e)_k$, is shown to be proportional to the inverse of the temperature of phase k , alike for the single phase Euler equations [5, 6]. The right hand-side of Eq. (7) is unconditionally positive since all terms are squared and thus, is used to demonstrate the entropy minimum principle. Furthermore, Eq. (7) is valid for both phases $\{k, j\}$ and ensures positivity of the total entropy equation that is obtained by summing

51 over the phases:

$$\sum_k (s_e)_k^{-1} \alpha_k \rho_k A \frac{Ds_k}{Dt} = \sum_k (s_e)_k^{-1} \alpha_k \rho_k A (\partial_t s_k + \mathbf{u}_k \cdot \nabla s_k) \geq 0. \quad (8)$$

52 Note that when one phase disappears, Eq. (8) degenerates into the single phase
53 entropy equation obtained from the multi-D Euler equations [1, 6].

54 **3. A viscous regularization for the seven-equation two-phase flow** 55 **model**

56 We now propose to derive a viscous regularization for the seven-equation
57 model given in Eq. (1) by using the same methodology as for the multi-D Euler
58 equations with/without variable area [5, 7]. The method consists in adding dis-
59 sipative terms to the system of equation under consideration, and re-derive the
60 entropy equation whose sign is known to be positive to ensure uniqueness of the
61 numerical solution [8]. Because of the addition of dissipation terms, the entropy
62 equation is modified and contains extra terms of yet unknown sign. By carefully
63 choosing a definition for each of the dissipation term, the sign of the entropy
64 equation can be determined and proved positive. For the seven-equation model,
65 derivation of a viscous regularization can be achieved by considering either the
66 phasic entropy equation (Eq. (7)) or the total entropy equation (Eq. (8)). In the
67 later case, the entropy minimum principle is verified for the whole system which
68 may not ensure positivity of the entropy equation for each phase. However,
69 positivity of the total entropy equation can be also achieved by assuming that
70 the entropy minimum principle holds for each phase. This stronger requirement
71 will also ensure consistency with the single phase Euler equations when one of
72 the phase disappears in the limit $\alpha_k \rightarrow 0$. Thus, it is chosen to work with the
73 phasic entropy equations given in Eq. (7).

For the purpose of this section, the system of equations given in Eq. (9) is considered, which is obtained by simply omitting the mass source terms (terms proportional to Γ) in Eq. (1) (source terms will be dealt with later, in SECTION).

$$\partial_t (\alpha_k A) + A \mathbf{u}_{int} \cdot \nabla \alpha_k = A \mu_P (P_k - P_j) \quad (9a)$$

$$\partial_t (\alpha_k \rho_k A) + \nabla \cdot (\alpha_k \rho_k \mathbf{u}_k A) = 0 \quad (9b)$$

$$\begin{aligned} \partial_t (\alpha_k \rho_k u_k A) + \nabla \cdot [\alpha_k A (\rho_k \mathbf{u}_k \otimes \mathbf{u}_k + P_k \mathbb{I})] = \\ \alpha_k P_k \nabla A + P_{int} A \nabla \alpha_k + A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) \end{aligned} \quad (9c)$$

$$\begin{aligned} \partial_t (\alpha_k \rho_k E_k A) + \nabla \cdot [\alpha_k A \mathbf{u}_k (\rho_k E_k + P_k)] = \\ A P_{int} \mathbf{u}_{int} \cdot \nabla \alpha_k - \mu_P \bar{P}_{int} (P_k - P_j) + A \lambda_u \bar{\mathbf{u}}_{int} \cdot (\mathbf{u}_j - \mathbf{u}_k) \end{aligned} \quad (9d)$$

In order to apply the entropy viscosity method, dissipation terms are added to each equation yielding:

$$\partial_t (\alpha_k A) + A \mathbf{u}_{int} \cdot \nabla \alpha_k = A \mu_P (P_k - P_j) + \nabla \cdot \mathbf{l}_k \quad (10a)$$

$$\partial_t (\alpha_k \rho_k A) + \nabla \cdot (\alpha_k \rho_k \mathbf{u}_k A) = \nabla \cdot \mathbf{f}_k \quad (10b)$$

$$\begin{aligned} \partial_t (\alpha_k \rho_k \mathbf{u}_k A) + \nabla \cdot [\alpha_k A (\rho_k \mathbf{u}_k \otimes \mathbf{u}_k + P_k \mathbb{I})] = \\ \alpha_k P_k \nabla A + P_{int} A \nabla \alpha_k + A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) + \nabla \cdot \mathfrak{g}_k \end{aligned} \quad (10c)$$

$$\begin{aligned} \partial_t (\alpha_k \rho_k E_k A) + \nabla \cdot [\alpha_k A \mathbf{u}_k (\rho_k E_k + P_k)] = \\ P_{int} A \mathbf{u}_{int} \cdot \nabla \alpha_k - \mu_P \bar{P}_{int} (P_k - P_j) + A \lambda_u \bar{\mathbf{u}}_{int} \cdot (\mathbf{u}_j - \mathbf{u}_k) \\ + \nabla \cdot (\mathbf{h}_k + \mathbf{u} \cdot \mathfrak{g}_k) \end{aligned} \quad (10d)$$

where \mathbf{f}_k , \mathfrak{g}_k , \mathbf{h}_k and \mathbf{l}_k are phasic viscous terms to be determined. The next step consists in deriving the entropy equation for the phase k , on the same model as what was done in Appendix A but with dissipative terms now present. The steps are as follows:

1. derive the phasic density and internal energy equations from Eq. (10).
2. assuming that the phasic entropy, s_k , is a function of density, ρ_k and internal energy, e_k , derive the entropy equation by using the chain rule:

$$\frac{Ds_k}{Dt} = (s_\rho)_k \frac{D\rho_k}{Dt} + (s_e)_k \frac{De_k}{Dt} \quad (11)$$

The terms $(s_e)_k$ and $(s_\rho)_k$ denote the partial derivative of the entropy s_k with respect to e_k and ρ_k , respectively.

3. isolate the terms of interest and choose an appropriate expression for each of the dissipation terms in order to ensure positivity of the new entropy residual.

We first derive the phasic density equation for the primitive variable ρ_k by combining Eq. (10a) and Eq. (10b) to obtain:

$$\alpha_k A \left[\partial_t \rho_k + (\mathbf{u}_k - \underline{\mathbf{u}_{int}}) \cdot \nabla \rho_k \right] = \underline{\underline{A \rho_k \mu_P (P_k - P_j)}} + \nabla \cdot \mathbf{f}_k - \rho_k \nabla \cdot \mathbf{l}_k \quad (12)$$

In order to derive the phasic internal energy equation, the phasic velocity equation is obtained by subtracting the phasic density equation from the phasic momentum equation:

$$\begin{aligned} \alpha_k \rho_k A [\partial_t \mathbf{u}_k + \mathbf{u}_k \cdot \nabla \mathbf{u}_k] + \nabla \cdot (\alpha_k \rho_k A P_k \mathbb{I}) = \\ \alpha_k P_k \nabla A + P_{int} A \nabla \alpha_k + A \lambda (\mathbf{u}_j - \mathbf{u}_k) + \nabla \cdot \mathfrak{g}_k - \mathbf{u}_k \otimes \mathbf{f}_k \end{aligned} \quad (13)$$

After multiplying Eq. (13) by the phasic velocity vector \mathbf{u}_k , the resulting phasic kinetic energy equation is subtracted from the phasic total energy equation to obtain the internal energy equation for phase k :

$$\begin{aligned} \alpha_k \rho_k A [\partial_t \mathbf{e}_k + \mathbf{u}_k \cdot \nabla \cdot \mathbf{e}_k] + \alpha_k \rho_k A P_k \nabla \mathbf{u}_k = \\ \underline{\underline{P_{int} A (\mathbf{u}_{int} - \mathbf{u}_k) \cdot \nabla \alpha_k - \alpha_k P_k \mathbf{u}_k \cdot \nabla A}} \\ \underline{\underline{-\bar{P}_{int} A \mu_P (P_k - P_j) + A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) \cdot (\bar{\mathbf{u}}_{int} - \mathbf{u}_k)}} \\ + \nabla \cdot \mathbf{h}_k + \mathfrak{g}_k : \nabla \mathbf{u}_k + \|\mathbf{u}\|_k^2 \mathbf{f}_k \end{aligned} \quad (14)$$

The underline terms in Eq. (12) and Eq. (14) yield the positive terms in the right-hand-side of Eq. (7) and thus are ignored in the remainder of this derivation for brevity. The phasic entropy equation is now obtained by combining the phasic density equation (Eq. (12)) and the phasic internal energy equation (Eq. (14)) through the chain rule given in Eq. (11) to yield:

$$\begin{aligned} \alpha_k \rho_k A \frac{Ds_k}{Dt} = (\rho s_\rho)_k [\nabla \cdot \mathbf{f}_k - \rho_k \nabla \cdot \mathbf{l}_k] + \\ (s_e)_k [\nabla \cdot \mathbf{h}_k + \mathfrak{g}_k : \nabla \mathbf{u}_k + (\|\mathbf{u}\|_k^2 - e_k) \nabla \cdot \mathbf{f}_k], \end{aligned} \quad (15)$$

where it was assumed that the entropy of phase k satisfies the second thermodynamic law:

$$T_k ds_k = de_k - P_k \frac{d\rho_k}{\rho_k^2}, \quad (16a)$$

which implies

$$P_k (s_e)_k + \rho_k (s_\rho)_k = 0, \quad (16b)$$

$$(s_e)_k = T_k^{-1} \text{ and } (s_\rho)_k = -(s_e)_k P_k \frac{d\rho_k}{\rho_k^2}.$$

Following the methodology applied in [5, 7], the right-hand side of Eq. (15) can be further simplified by using the following expression for the dissipative terms \mathbf{f}_k , \mathfrak{g}_k and \mathbf{h}_k :

$$\mathbf{f}_k = \tilde{\mathbf{f}}_k + \rho_k \mathbf{l}_k \quad (17a)$$

$$\mathfrak{g}_k = \alpha_k \rho_k A \mu_k \mathbb{F}(\mathbf{u}_k) + \mathbf{f}_k \otimes \mathbf{u}_k \quad (17b)$$

$$\mathbf{h}_k = \tilde{\mathbf{h}}_k - \frac{\|\mathbf{u}_k\|^2}{2} \mathbf{f}_k + (\rho e)_k \mathbf{l}_k, \quad (17c)$$

where μ_k is a positive viscosity coefficient for phase k . Note the area function A in the definition of \mathfrak{g}_k . Substituting the expression of the dissipative terms

given in Eq. (17) into Eq. (15) yields:

$$\begin{aligned}
\alpha_k \rho_k A \frac{Ds_k}{Dt} &= \underbrace{\nabla \cdot \left[(s_e)_k \tilde{\mathbf{h}}_k + \left(e_k (s_e)_k - \rho_k (s_\rho)_k \right) \tilde{\mathbf{f}}_k \right]}_{\mathcal{R}_0} \\
&\quad \underbrace{(s_e)_k \alpha_k \rho_k A \mu_k \mathbb{F}(\mathbf{u}_k) : \nabla \mathbf{u}_k}_{\mathcal{R}_1} - \underbrace{\tilde{\mathbf{h}}_k \cdot \nabla (s_e)_k - \tilde{\mathbf{f}}_k \cdot \nabla [(e s_e)_k - (\rho s_\rho)_k]}_{\mathcal{R}_2} + \\
&\quad \underbrace{(s_e)_k \nabla \cdot (\rho_k e_k \mathbf{l}_k) - (s_e)_k e_k \nabla \cdot (\rho_k \mathbf{l}_k) + \rho_k (s_\rho)_k \nabla \cdot (\rho_k \mathbf{l}_k) - \rho_k^2 (s_\rho)_k \nabla \cdot \mathbf{l}_k}_{\mathcal{R}_3}. \quad (18)
\end{aligned}$$

We now split the right-hand-side of Eq. (18) into three residuals denoted by \mathcal{R}_1 , \mathcal{R}_2 and \mathcal{R}_3 and we study the sign of each of them. Since $(s_e)_k$ is defined as the inverse of the temperature and thus is positive, the sign of the first term, \mathcal{R}_1 , is conditioned by the choice of the function $\mathbb{F}(\mathbf{u}_k)$ so that the product with the tensor $\nabla \mathbf{u}_k$ is positive. As in [5, 7], $\mathbb{F}(\mathbf{u}_k)$ is chosen proportional to the symmetric gradient of the velocity vector $\nabla^s \mathbf{u}_k$, whose entries are given by $((\nabla^s \mathbf{u})_{i,j})_k = \frac{1}{2} (\partial_{x_i} u_j + \partial_{x_j} u_i)_k$. With such a choice, the viscous regularization is also rotationally invariant. After a few lines of algebra, the third term \mathcal{R}_3 can be recast as a function of the gradient of the entropy as follows:

$$\mathcal{R}_3 = \rho_k A \mathbf{l}_k \cdot \nabla s_k. \quad (19)$$

88 One of the assumptions made in the entropy minimum principle is to that the
 89 entropy is at a minimum which implies that its gradient is null. Because of
 90 this, it follows that the term \mathcal{R}_3 is zero at the minimum and thus, the entropy
 91 minimum principle is verified independently of the definition of the dissipation
 92 term \mathbf{l}_k used in the volume fraction equation Eq. (10a). It will be explained
 93 later in this section how to obtain a definition for \mathbf{l}_k .

We now focus on the term denoted by \mathcal{R}_2 , which is identical to the right-hand-side of the single phase entropy equation for Euler equations (see [5, 7]). Thus, the term \mathcal{R}_2 is known to be positive when (i) assumes concavity of the entropy function s_k with respect to the internal energy e_k and the specific volume $1/\rho_k$ (or convexity of $-s_k$) and (ii) chooses the following definitions for the dissipative terms $\tilde{\mathbf{h}}_k$ and $\tilde{\mathbf{f}}_k$:

$$\tilde{\mathbf{f}}_k = \alpha_k A \kappa_k \nabla \rho_k \quad (20a)$$

$$\tilde{\mathbf{h}}_k = \alpha_k A \kappa_k \nabla (\rho e)_k, \quad (20b)$$

94 where κ_k is another positive viscosity coefficient. In addition, using Eq. (20a),
 95 the term \mathcal{R}_0 can be recast as a function of the phasic entropy as follows:

$$\mathcal{R}_0 = \nabla \cdot (\alpha_k A \kappa_k \rho_k \nabla s_k) \quad (21)$$

The entropy equation can now be written in its final form:

$$\begin{aligned}
\alpha_k \rho_k A \frac{Ds_k}{Dt} &= \mathbf{f}_k \cdot \nabla s_k + \nabla \cdot (\alpha_k A \rho_k \kappa_k \nabla s_k) \\
&\quad - \alpha_k \rho_k A \kappa_k \mathbf{Q}_k + (s_e)_k \alpha_k A \rho_k \mu_k \nabla^s \mathbf{u}_k : \nabla \mathbf{u}_k, \quad (22)
\end{aligned}$$

96 where \mathbf{Q}_k is a negative semi-definite quadratic form under the assumption of s_k
 97 being concave with respect to e_k and $1/\rho_k$, and defined as:

$$\begin{aligned} \mathbf{Q}_k &= X_k^t \Sigma_k X_k \\ \text{with } X_k &= \begin{bmatrix} \nabla \rho_k \\ \nabla e_k \end{bmatrix} \text{ and } \Sigma_k = \begin{bmatrix} \rho_k^{-2} \partial_{\rho_k} (\rho_k^2 \partial_{\rho_k} s_k) & \partial_{\rho_k, e_k} s_k \\ \partial_{\rho_k, e_k} s_k & \partial_{e_k, e_k} s_k \end{bmatrix}. \end{aligned}$$

98 Eq. (22) is used to prove the entropy minimum principle: assuming that s_k
 99 reaches its minimum value in $\mathbf{r}_{min}(t)$ at each time t , the gradient, ∇s_k , and
 100 Laplacian, Δs_k , of the entropy are null and positive at this particular point,
 101 respectively. Furthermore, it is recalled that the viscosity coefficients μ_k and
 102 κ_k are positive by definition. Then, because the terms in the right-hand-side of
 103 Eq. (22) are proven either positive or null when the entropy reaches a minimum
 104 value, the entropy minimum principle holds for each phase k , **independently**
 105 **of the definition of the dissipative term \mathbf{l}_k** , such as:

$$\alpha_k \rho_k A \partial_t s_k(\mathbf{r}_{min}, t) \geq 0 \Rightarrow \partial_t s_k(\mathbf{r}_{min}, t) \geq 0$$

106 [Do we need to make the above statement a theorem or property?](#)

107 It remains to obtain a definition for the dissipative term \mathbf{l}_k used in the
 108 volume fraction equation Eq. (10a). A way to achieve this is to consider the
 109 volume fraction equation, by itself and notice that it is an hyperbolic equation
 110 with eigenvalue \mathbf{u}_{int} . An entropy equation can be derived and used to prove
 111 the entropy minimum principle by properly choosing the dissipative term. The
 112 objective is to ensure positivity of the volume fraction and also uniqueness of
 113 the weak solution. Following the work of Guermond et al. in [9, 10], it can be
 114 shown that a dissipative term ensuring positivity and uniqueness of the weak
 115 solution for the volume fraction equation, is of the form $\mathbf{l}_k = \beta_k A \nabla \alpha_k$, where
 116 β_k is a positive viscosity coefficient. The dissipative term is proportional to the
 117 area A for consistency with the other terms of the volume fraction equation
 118 Eq. (10a).

All of the dissipative terms are now defined and recalled here:

$$\mathbf{l}_k = \beta_k A \nabla \alpha_k \quad (23a)$$

$$\mathbf{f}_k = \alpha_k A \kappa_k \nabla \rho_k + \rho_k A \mathbf{l}_k \quad (23b)$$

$$\mathbf{g}_k = \alpha_k A \mu_k \rho \nabla^s \mathbf{u}_k \quad (23c)$$

$$\mathbf{h}_k = \alpha_k A \kappa_k \nabla (\rho e)_k + \mathbf{u}_k : \mathbf{g}_k - \frac{\|\mathbf{u}_k\|^2}{2} \mathbf{f}_k + (\rho e)_k \mathbf{l}_k \quad (23d)$$

119 At this point, some remarks are in order:

1. The viscous regularization given in Eq. (23) for the multi-D seven-equation model, is equivalent to the parabolic regularization [11] when assuming $\beta_k = \kappa_k = \mu_k$ and $\mathbb{F}(\mathbf{u}_k) = \alpha_k \rho_k \kappa_k \nabla \mathbf{u}_k$, but is no longer rotation invariant. However, decoupling between the regularization on the velocity and on the density in the momentum equation is important to make the regularization rotation invariant but also to ensure well-scaled dissipative terms for a wide range of Mach number as was shown in [7] for the multi-D Euler equations.
2. The dissipative term \mathbf{l}_k requires the definition of a new viscosity coefficient β_k . It was shown that this viscosity coefficient is independent of the other viscosity coefficients μ_k and κ_k . Its definition should account for the eigenvalue \mathbf{u}_{int} and the entropy equation associated with the volume fraction equation.
3. The dissipative term \mathbf{f}_k is a function of \mathbf{l}_k . Thus, all of the other dissipative terms are also functions of \mathbf{l}_k .
4. The partial derivatives $(s_e)_k$ and $(s_{\rho_k})_k$ can be computed using the definition provided in Eq. (16a) and are functions of the phasic thermodynamic variables: pressure, temperature and density.
5. All of the dissipative terms are chosen to be proportional to the void fraction α_k and the cross-sectional area A , except the one in the volume fraction equation that is only proportional to A . For instance, $\alpha_k A \nabla \rho_k$ is the flux of the dissipative term in the continuity equation through the pseudo-area, $\alpha_k A$, seen by the phase k . When one of the phases disappears, the dissipative terms must go to zero for consistency. On the other hand, when α_k goes to one, the single-phase Euler equations with variable area and with proper viscous regularization must be recovered.
6. Compatibility of the viscous regularization proposed in Eq. (23) with the generalized entropies identified in Harten et al. [12] is demonstrated in Appendix B.

At this point in the paper, we have derived a viscous regularization for the multi-D seven-equation two-phase flow model that ensures positivity of the entropy residual, uniqueness of the numerical solution when assuming concavity of the phasic entropy s_k , and is consistent with the viscous regularization derived for the multi-D Euler equations [5, 7] in the limit $\alpha_k \rightarrow 1$. The viscous regularization involves a set of three viscosity coefficients for each phase, μ_k , κ_k and β_k , that are assumed positive. Definition of the viscosity coefficients is now required to complete the numerical stabilization method. Since the focus of this paper is the entropy viscosity method, the viscosity coefficients will be defined function of entropy residuals in Section 4. However, one can also devise a definition for the viscosity coefficients μ_k and κ_k by analogy to Lapidus [13, 14] or some pressure-based methods [15] used for the single-phase Euler equations. On the other hand, the viscosity coefficient, β_k , for the volume fraction equation should rely on artificial dissipation stabilization methods used for scalar hyperbolic equations.

Remark. *Through the derivations of the viscous regularization, it was noted*

that another set of dissipative terms \mathbf{f}_k and \mathbf{l}_k would also ensures positivity of the entropy residual:

$$\mathbf{l}_k = \beta_k T_k \left[\frac{\rho_k}{P_k + \rho_k e_k} \nabla \left(\frac{P_k}{\rho_k e_k} \right) - \frac{1}{P_k} \nabla \rho_k \right] \quad (24a)$$

$$\mathbf{f}_k = \kappa_k \nabla \rho_k + \frac{\rho_k^2 (s_\rho)_k}{(\rho s_\rho - e s_e)_k} \mathbf{l}_k \quad (24b)$$

164 However, the definition of \mathbf{l}_k proposed in Eq. (24a) was not considered as valid
 165 for the following reasons: positivity of the volume fraction cannot be achieved
 166 and the parabolic regularization is not retrieved when assuming equal viscosity
 167 coefficients.

168 4. An all-speed formulation of the Entropy Viscosity Method

169 When working with artificial dissipative numerical stabilization methods,
 170 great care needs to be carried to the definition of the viscosity coefficients that
 171 will determine the accuracy of the method. Generally speaking, sufficient artificial
 172 viscosity should be added into the shock and discontinuity regions to prevent
 173 spurious oscillations from forming, while little dissipation is added when the
 174 numerical solution is smooth. Such requirements can be achieved by tracking
 175 shocks and discontinuities in the numerical solutions. When dealing with fluid
 176 equations, the low-Mach asymptotic limit also has to be accounted for in the
 177 definition of the viscosity coefficients in order to ensure well-scaled dissipative
 178 terms [16, 17, 18]. Also, because each phase can experience different flow regime
 179 e.g., supersonic gas and subsonic liquid, it is chosen to work with three distinct
 180 viscosity coefficients for each phase. The purpose of this section is to derive a
 181 definition for the phasic viscosity coefficients, μ_k , κ_k and β_k , that ensures the
 182 correct numerical solution in the low-Mach limit, can accurately resolves shocks
 183 in transonic and supersonic flows and is also consistent with the definition of
 184 the viscosity coefficients devised for the single-phase Euler equations in the limit
 185 $\alpha_k \rightarrow 1$. As a result, the approach used in [7] will be applied here in this section.

186 4.1. Definition of the viscosity coefficients

In the entropy viscosity method, each viscosity coefficient is function of an upper and a lower bound that are referred to as first-order viscosity coefficient and entropy viscosity coefficient (high-order coefficient), respectively, as shown in Eq. (25). The first-order viscosity coefficient is denoted by the subscript *max* and is defined proportional to the largest local eigenvalue so that the stabilization scheme becomes over-dissipative and smooth out all discontinuities when the entropy residual is large. The entropy viscosity coefficient is set proportional to an entropy residual and jumps of quantities to determine, and denoted by

the subscript e .

$$\begin{aligned}\beta_k(\mathbf{r}, t) &= \min(\beta_{e,k}(\mathbf{r}, t), \beta_{max,k}(\mathbf{r}, t)), \\ \mu_k(\mathbf{r}, t) &= \min(\mu_{e,k}(\mathbf{r}, t), \mu_{max,k}(\mathbf{r}, t)), \\ \kappa_k(\mathbf{r}, t) &= \min(\kappa_{e,k}(\mathbf{r}, t), \kappa_{max,k}(\mathbf{r}, t)),\end{aligned}\tag{25}$$

where all of the variables are locally defined. We now define the first-order viscosity coefficients and will focus first on the phasic viscosity coefficients κ_k and μ_k that are intimately linked to the mass, momentum and energy equations. These two viscosity coefficients are involved in dissipative terms that identical to the ones obtained for the single-phase Euler equations [5, 7] when seeing the term $\alpha_k A$ as a pseudo cross-section and assuming an uniform volume fraction profile. Thus, it is chosen to define the corresponding first-order viscosity coefficients proportional to the local largest eigenvalue $\|\mathbf{u}_k\| + c_k$ as follows:

$$\kappa_{max,k}(\mathbf{r}, t) = \mu_{max,k}(\mathbf{r}, t) = \frac{h}{2} (\|\mathbf{u}_k\|(\mathbf{r}, t) + c_k(\mathbf{r}, t)),\tag{26}$$

where h is the grid size (each phase is solved on the same mesh). It remains to define the first-order viscosity coefficient, $\beta_{max,k}$, used in the volume fraction equation. Because the volume fraction equation can be treated as a hyperbolic scalar equation with an unique eigenvalue \mathbf{u}_{int} , the first-order viscosity coefficient is defined by analogy with Burger's equation [9, 10] as follows:

$$\beta_{max,k}(\mathbf{r}, t) = \frac{h}{2} \|\mathbf{u}_{int}(\mathbf{r}, t)\|.\tag{27}$$

After defining the first-order viscosity coefficients for each phase, we focus our attention to the entropy viscosity coefficients denoted by the subscript e in Eq. (25). We first choose to investigate the definitions of $\mu_{e,k}$ and $\kappa_{e,k}$. The entropy viscosity coefficients are set proportional to the entropy residual given in Eq. (28), that is known to be positive and peaked in the shock region.

$$R_k(\mathbf{r}, t) := \frac{Ds_k}{Dt} = \partial_t s_k + \mathbf{u}_k \cdot \nabla s_k\tag{28}$$

It is also accounted for the jumps of quantities that will be determined further. The objective is to be able to track spatially and temporally any shock and discontinuity forming in the computational domain. In [7], it was demonstrated the usefulness of recasting the entropy residual as a function of pressure, velocity, density and speed of sound as shown in Eq. (29). The alternative expression of the entropy residual denoted by $\tilde{R}_k(\mathbf{r}, t)$, no longer requires an analytical expression of the entropy s_k and experiences the same variations (in absolute value) as the original definition of the entropy residual (Eq. (28)).

$$R_k(\mathbf{r}, t) = \frac{Ds_k}{Dt} = \frac{(s_e)_k}{(P_e)_k} \underbrace{\left(\frac{DP_k}{Dt} - c_k^2 \frac{D\rho_k}{Dt} \right)}_{\tilde{R}_k(\mathbf{r}, t)},\tag{29}$$

213 Using the new expression of the entropy residual \tilde{R}_k , we now propose a defini-
 214 tion, given in Eq. (30), for the phasic entropy viscosity coefficients $\mu_{e,k}$ and $\kappa_{e,k}$
 215 that also accounts for jumps, J_k , of some function of the pressure and density for
 216 generality purpose. The jump helps at tracking contact waves or discontinuities
 217 other than shock that are not seen by the entropy residual. Its definition will
 218 be detailed in Section 4. A distinct normalization parameter is also introduced
 219 for each viscosity coefficient that is used for dimensionality purpose: a quick
 220 dimensional study of the dissipative terms shows that the viscosity coefficients
 221 are kinematic viscosity ($m^2 \cdot s^{-1}$). Thus, the normalization parameters has units
 222 in pressure and its final definition will be determined by a low-Mach asymptotic
 223 limit of Eq. (10) in order to ensure well-scaled dissipative terms for all-Mach
 224 flows. We see here the advantage of using the new expression for the entropy
 225 residual \tilde{R}_k that offers more diversity in the choice of the normalization param-
 226 eters: the pressure itself and combination of the density, the sound speed and
 227 the norm of the velocity.

$$\mu_{e,k}(\mathbf{r}, t) = h^2 \frac{\max \left(|\tilde{R}_k(\mathbf{r}_q, t)|, \|J_k^\mu\| \right)}{\text{norm}_{P,k}^\mu}, \quad (30a)$$

228 and

$$\kappa_{e,k}(\mathbf{r}, t) = h^2 \frac{\max \left(|\tilde{R}_k(\mathbf{r}_q, t)|, \|J_k^\kappa\| \right)}{\text{norm}_{P,k}^\kappa}. \quad (30b)$$

It remains to define the entropy viscosity coefficient $\beta_{e,k}$. For the purpose of this paragraph, let us consider the scalar volume fraction equation and assume that the interface velocity \mathbf{u}_{int} is given. Because it is a scalar hyperbolic equation, it is proposed to define the entropy viscosity coefficients on the same model as what is done for Burger's equation [9, 10]. Thus, the entropy viscosity coefficient β_e is defined as a function of an entropy residual, R_k^α , derived from the volume fraction equation for phase k , and the jump of a function of the volume fraction, J_k^α , as shown in Eq. (31).

$$\beta_{e,k}(\mathbf{r}, t) = h^2 \frac{\max \left(|R_k^\alpha(\mathbf{r}_q, t)|, \|J_k^\alpha\| \right)}{\text{norm}_{\alpha,k}^\beta} \quad (31)$$

229 We also introduce a normalization parameter, $\text{norm}_{\alpha,k}^\beta$, whose expression will
 230 be further investigated in Section 4.2. To derive the entropy residual, $R_{\alpha,k}$, we
 231 consider the volume fraction equation for phase k with its viscous regularization
 232 and assume the existence of an entropy denoted by $\eta_k(\alpha_k)$ [8]:

$$\partial_t (A\alpha_k) + A\mathbf{u}_{int} \cdot \nabla \alpha_k = \nabla \cdot (\beta_k A \nabla \alpha_k) \quad (32)$$

233 After multiplying by $\frac{d\eta(\alpha_k)}{d\alpha_k}$ and using the chain rule, an expression for the
 234 entropy equation is obtained:

$$\underbrace{\partial_t (A\eta(\alpha_k)) + A\mathbf{u}_{int} \cdot \nabla \eta(\alpha_k)}_{R_k^\alpha} = \frac{d\eta(\alpha_k)}{d\alpha_k} \nabla \cdot (\beta_k A \nabla \alpha_k) \quad (33)$$

235 The entropy residual, R_k^α , is defined as the left hand side of Eq. (33) and is
 236 known to be peaked in the shock region and positive when assuming convexity
 237 of the entropy η_k with respect to α_k [8]. Such a behavior is identical to the
 238 entropy residual \tilde{R}_k defined in Eq. (29), and will allow detection of the shock
 239 wave in the volume fraction profile when used in the definition of the entropy
 240 viscosity coefficient $\beta_{e,k}$.

241 At this point of the paper, the definition of the viscosity coefficients are
 242 not finalized: the jumps and normalization parameters still have to be defined.
 243 Details regarding the definition of the jump will be given in Section 5. The
 244 normalization parameters are derived from a low-Mach asymptotic limit analysis
 245 which is the purpose of the next section.

246 4.2. Asymptotic study in the low-Mach regime

247 Developing a numerical method for fluid equations require to investigate
 248 the low-Mach asymptotic limit. In this particular limit, numerical methods
 249 developed for transonic and supersonic flows usually fail due to ill-scaled dissipa-
 250 tive terms. A fix can be found by performing a low-Mach asymptotic limit
 251 to ensure well-scaled dissipative terms [16, 17, 18]. Then, it is proposed to
 252 perform a low-Mach asymptotic limit to derive a definition for the phasic nor-
 253 malization parameters introduced in Section 4.1. We consider the case where
 254 the relaxation coefficients are set to zero: the two phases do not interact and
 255 the seven-equation model degenerates into two sets of Euler equations with a
 256 pseudo cross-section $\alpha_k A$. Two limit cases (a) and (b) will be considered to
 257 determine appropriate scaling for the entropy viscosity coefficients so that the
 258 dissipative terms remain well-scaled for: (a) the isentropic low-Mach limit where
 259 the seven-equation model degenerate to an incompressible system of equations
 260 in the low-Mach limit and (b) the non-isentropic limit with formation of shocks.
 261 In the low-Mach limit, the isentropic limit of the seven-equation model with vis-
 262 cous regularization should yield incompressible fluid flow solutions (the seven-
 263 equation model was derived by assuming that each phase obeys the multi-D
 264 Euler equations), namely, that the phasic pressure fluctuations are of the order
 265 M_k^2 and that the velocity satisfies the divergence constraint $\nabla \cdot (\vec{u}A)_k = 0$
 266 [16, 17, 18]. For non-isentropic situations, shocks may form for any value of
 267 Mach number (a step initial pressure will always yield a shock wave) and the
 268 minimum entropy principle should still be satisfied so that numerical oscilla-
 269 tions, if any, be controlled by the entropy viscosity method independently of
 270 the value of the Mach number. For each case the scaling of the numerical adi-
 271 mensional numbers will be given along with the definition of the normalization
 272 parameters defined in Section 4.1 for each viscosity coefficients. The asymptotic
 273 study is performed on the multi-D version of the seven-equation model with the
 274 Stiffened Gas Equation of State (SGEOS) given in Eq. (34).

$$P_k = (\gamma_k - 1) \rho_k e_k - \gamma_k P_{k,\infty} \quad (34)$$

The first step in the study of the two limit cases (a) and (b) is to re-write
 each system of equations in a non-dimensional manner. To do so, the following

variables are introduced for each phase k :

$$\begin{aligned}\rho_k^* &= \frac{\rho_k}{\rho_{k,\infty}}, \quad u_k^* = \frac{\mathbf{u}_k}{u_{k,\infty}}, \quad P_k^* = \frac{P_k}{\rho_{k,\infty} c_{k,\infty}^2}, \quad E_k^* = \frac{E_k}{c_{k,\infty}^2}, \quad x^* = \frac{x}{L_\infty}, \\ t_k^* &= \frac{t_k}{L_\infty / u_{k,\infty}}, \quad \mu_k^* = \frac{\mu_k}{\mu_{k,\infty}}, \quad \kappa_k^* = \frac{\kappa_k}{\kappa_{k,\infty}}, \quad P_{int}^* = \frac{P_{int}}{P_{int,\infty}}, \\ u_{int}^* &= \frac{u_{int}}{u_{int,\infty}}, \quad \bar{P}_{int}^* = \frac{\bar{P}_{int}}{\bar{P}_{int,\infty}}, \quad \bar{u}_{int}^* = \frac{\bar{u}_{int}}{\bar{u}_{int,\infty}},\end{aligned}\quad (35)$$

where the subscript ∞ denote the far-field or stagnation quantities and the superscript $*$ stands for the non-dimensional variables. The far-field reference quantities are chosen such that the dimensionless flow quantities are of order 1. The stagnation quantities for the pressure and velocity interfacial variables will be specified for each case. The reference Mach number is given by

$$M_{k,\infty} = \frac{u_{k,\infty}}{c_{k,\infty}}. \quad (36)$$

Because we consider that phases do not interact with each other, it is assumed that the interfacial pressure and velocity scale as the phasic pressure and velocity, respectively: $P_{int,\infty} = \rho_{k,\infty} c_{k,\infty}^2$ and $u_{int,\infty} = u_{k,\infty}$. Under these assumptions, the interfacial pressure and velocity are simply replaced by P_k and \mathbf{u}_k in the equations. Then, the system of equations with viscous regularization becomes:

$$\partial_t (\alpha_k A) + A \mathbf{u}_k \cdot \nabla \alpha_k = \nabla \cdot (A \beta_k \nabla \alpha_k) \quad (37a)$$

$$\partial_t (\alpha_k \rho_k A) + \nabla \cdot (\alpha_k \rho_k \mathbf{u}_k A) = \nabla \cdot (A \alpha_k \kappa_k \nabla \rho_k) + \nabla \cdot (A \beta_k \rho_k \nabla \alpha_k) \quad (37b)$$

$$\begin{aligned}\partial_t (\alpha_k \rho_k u_k A) + \nabla \cdot [\alpha_k A (\rho_k \mathbf{u}_k \otimes \mathbf{u}_k + P_k)] = \\ \alpha_k P_k \nabla A + P_k A \nabla \alpha_k + \nabla \cdot (A \mu_k \alpha_k \rho_k \nabla^s \mathbf{u}_k) + \\ \nabla \cdot (A \kappa_k \alpha_k \mathbf{u}_k \otimes \nabla \rho_k) + \nabla \cdot (A \beta_k \rho_k \mathbf{u}_k \otimes \nabla \alpha_k)\end{aligned}\quad (37c)$$

$$\begin{aligned}\partial_t (\alpha_k \rho_k E_k A) + \nabla \cdot [\alpha_k A \mathbf{u}_k (\rho_k E_k + P_k)] = \\ P_k A \mathbf{u}_k \cdot \nabla \alpha_k + \nabla \cdot (A \kappa_k \alpha_k \nabla (\rho_k e_k)) + \\ \nabla \cdot \left(A \kappa_k \alpha_k \frac{||\mathbf{u}_k||^2}{2} \nabla \rho_k \right) + \nabla \cdot (A \mu_k \alpha_k \rho_k \mathbf{u}_k : \nabla^s \mathbf{u}_k) + \\ \nabla \cdot (A \beta_k \rho_k e_k \nabla \alpha_k)\end{aligned}\quad (37d)$$

Then using the scaling introduced in Eq. (35), the scaled equations for the phase k with viscous regularization are: [The following set of equations is very painful to read. I guess we can improve the format but I cannot think of a better way](#)

of presenting the scaled equations, unless we include all of this in an appendix (I am not for it)

$$\partial_{t^*} (\alpha_k A)^* + A^* \mathbf{u}_k^* \cdot \nabla^* \alpha_k^* = \frac{1}{\text{Pé}_{k,\infty}^\beta} \nabla^* \cdot (A \beta_k \nabla^* \alpha_k)^* \quad (38a)$$

$$\begin{aligned} \partial_{t^*} (\alpha_k \rho_k A)^* + \nabla^* \cdot (\alpha_k \rho_k \mathbf{u}_k A)^* &= \frac{1}{\text{Pé}_{k,\infty}^\kappa} \nabla^* \cdot (A \kappa_k \nabla^* \rho_k)^* + \\ &\frac{1}{\text{Pé}_{k,\infty}^\beta} \nabla^* \cdot (A \beta_k \rho_k \nabla^* \alpha_k)^* \end{aligned} \quad (38b)$$

$$\begin{aligned} \partial_{t^*} (\alpha_k \rho_k u_k A)^* + \nabla^* \cdot [\alpha_k A (\rho_k \mathbf{u}_k \otimes \mathbf{u}_k)]^* &+ \frac{A \alpha_k^*}{M_{k,\infty}^2} \nabla^* P_k^* = \\ \frac{1}{M_{k,\infty}^2} \alpha_k^* P_k^* \nabla^* A^* + \frac{1}{M_{k,\infty}^2} P_k^* A^* \nabla^* \alpha_k^* &+ \frac{1}{\text{Re}_{k,\infty}} \nabla^* \cdot (A \alpha_k \mu_k \rho_k \nabla^s \mathbf{u}_k)^* + \\ \frac{1}{\text{Pé}_{k,\infty}^\kappa} \nabla^* \cdot (A \alpha_k \kappa_k \mathbf{u}_k \otimes \nabla^* \rho_k)^* &+ \frac{1}{\text{Pé}_{k,\infty}^\beta} \nabla^* \cdot (A \beta_k \rho_k \mathbf{u}_k \otimes \nabla \alpha_k)^* \end{aligned} \quad (38c)$$

$$\begin{aligned} \alpha_k^* A^* [\partial_t (\rho_k E_k) + \mathbf{u}_k \cdot \nabla (\rho_k E_k)]^* &+ \alpha_k \nabla^* \cdot (A \mathbf{u}_k P_k) + \rho_k^* E_k^* \alpha_k^* \nabla^* \cdot (\mathbf{u}_k)_k^* = \\ \frac{1}{\text{Pé}_{k,\infty}^\kappa} \nabla^* \cdot (A \alpha_k \kappa_k \nabla (\rho_k e_k))^* &+ \frac{M_{k,\infty}^2}{\text{Pé}_{k,\infty}^\kappa} \nabla^* \cdot \left(A \alpha_k \kappa_k \frac{\|\mathbf{u}_k\|^2}{2} \nabla \rho \right)^* + \\ \frac{M_{k,\infty}^2}{\text{Re}_{k,\infty}} \nabla^* \cdot (A \alpha_k \mu_k \rho_k \mathbf{u}_k : \nabla^s \mathbf{u}_k)^* &+ \\ \frac{1}{\text{Pé}_{k,\infty}^\beta} \nabla (\rho_k e_k)^* \cdot (A \beta_k \nabla \alpha_k)^* &- \frac{M_{k,\infty}^2}{\text{Pé}_{k,\infty}^\beta} \rho_k \frac{\|\mathbf{u}_k^2\|}{2} \nabla \cdot (\beta_k A \nabla \alpha_k) \end{aligned} \quad (38d)$$

where the phasic numerical Reynolds ($\text{Re}_{k,\infty}$) and Péclet ($\text{Pé}_{k,\infty}^\kappa$ and $\text{Pé}_{k,\infty}^\beta$) numbers are defined as:

$$\text{Re}_{k,\infty} = \frac{u_{k,\infty} L_\infty}{\mu_{k,\infty}}, \text{Pé}_{k,\infty}^\kappa = \frac{u_{k,\infty} L_\infty}{\kappa_{k,\infty}} \text{ and } \text{Pé}_{k,\infty}^\beta = \frac{u_{k,\infty} L_\infty}{\beta_{k,\infty}}. \quad (39)$$

Note that the phasic energy equation was recast under a non-conservative form by using the volume fraction (Eq. (38a)) to facilitate the derivations when trying to recover the divergence constraint onto the velocity. The numerical Reynolds and Péclet numbers defined in Eq. (39) are related to the phasic entropy viscosity coefficients $\mu_{k,\infty}$, $\kappa_{k,\infty}$ and $\beta_{k,\infty}$. Thus, once a scaling (in powers of $M_{k,\infty}$) is obtained for $\text{Re}_{k,\infty}$, $\text{Pé}_{k,\infty}^\kappa$ and $\text{Pé}_{k,\infty}^\beta$, the corresponding normalization parameters $\text{norm}_{P,k}^\mu$, $\text{norm}_{P,k}^\kappa$ and $\text{norm}_{\alpha,k}^\beta$ will automatically be set. For brevity, the superscripts $*$ are omitted in the remainder of this section.

In the low-Mach isentropic limit, the seven-equation model converges to an incompressible system of equations when the Mach number tends to zero, that

292 is characterized with pressure fluctuations of order $M_{k,\infty}^2$ and the divergent
 293 constraint on the velocity: $\nabla \cdot (A\mathbf{u}_k) = 0$. When adding dissipative terms, as is
 294 the case with the entropy viscosity method, the main properties of the low-Mach
 295 asymptotic limit must be preserved. We begin by expanding each variable in
 296 powers of the Mach number. As an example, the expansion for the pressure is
 297 given by:

$$P_k(\mathbf{r}, t) = P_{k,0}(\mathbf{r}, t) + P_{k,1}(\mathbf{r}, t)M_{k,\infty} + P_{k,2}(\mathbf{r}, t)M_{k,\infty}^2 + \dots \quad (40)$$

298 By studying the resulting momentum equations for various powers of M_∞ , it
 299 is observed that the leading- and first-order pressure terms, $P_{k,0}$ and $P_{k,1}$, are
 300 spatially constant if and only if $\text{Re}_{k,\infty} = \text{Pe}_{k,\infty}^\kappa = \text{Pe}_{k,\infty}^\beta = 1$. In this case, we
 301 have at order $M_{k,\infty}^{-2}$:

$$\nabla P_{k,0} = 0 \quad (41a)$$

302 and at order $M_{k,\infty}^{-1}$

$$\nabla P_{k,1} = 0. \quad (41b)$$

303 From Eq. (41) we infer that the leading- and first-order pressure terms are
 304 spatially independent which ensures pressure fluctuations of order Mach num-
 305 ber square, as expected in the low-Mach asymptotic limit. Using the scaling
 306 $\text{Re}_{k,\infty} = \text{Pe}_{k,\infty}^\kappa = \text{Pe}_{k,\infty}^\beta = 1$, the second-order momentum equations and the
 307 leading-order expressions for the volume fraction, continuity and energy equa-
 308 tions are:

$$\partial_t (A\alpha_k)_0 + \mathbf{u}_{k,0} \cdot \nabla \alpha_{k,0} = \nabla \cdot (A\beta_k \nabla \alpha_k)_0 \quad (42a)$$

$$\partial_t (A\alpha_k \rho_k)_0 + \nabla \cdot (A\alpha_k \rho_k \mathbf{u}_k)_0 = \nabla \cdot (A\alpha_k \kappa_k \nabla \rho_k)_0 + \nabla \cdot (A\beta_k \nabla \alpha_k)_0 \quad (42b)$$

$$\begin{aligned} \partial_t (\alpha_k A \rho_k \mathbf{u}_k)_0 + \nabla \cdot (A\alpha_k \rho_k \mathbf{u}_k \otimes \mathbf{u}_k)_0 + A\alpha_k \nabla P_{k,2} = \\ \nabla \cdot [A\alpha_k (\mu_k \rho_k \nabla^s \mathbf{u}_k + \kappa_k \mathbf{u}_k \otimes \nabla \rho_k)]_0 + \nabla \cdot (A\beta_k \rho \mathbf{u} \nabla \alpha_k)_0 \end{aligned} \quad (42c)$$

$$\begin{aligned} \alpha_{k,0} A [\partial_t (\rho_k E_k) + \mathbf{u}_k \cdot \nabla (\rho_k E_k)]_0 + \alpha_{k,0} \nabla \cdot [A\mathbf{u}_k P_k]_0 + \alpha_{k,0} \rho_{k,0} E_{k,0} \nabla \cdot (\mathbf{u}_k A)_0 = \\ \nabla \cdot [A\alpha_k \kappa_k \nabla (\rho_k e_k)] + A\beta_{k,0} \nabla (\rho_k e_k)_0 \cdot \nabla \alpha_{k,0} \end{aligned} \quad (42d)$$

310 where the notation $(fg)_0$ means that we only keep the 0th-order terms in the
 311 product fg . The set of equations given in Eq. (42) are similar to the multi-D
 312 single-phase Euler equations with variable area when seeing $A\alpha_k$ as a pseudo-
 313 area [7]. The leading-order of the Stiffened Gas Equation of State (Eq. (34)) is
 314 given by

$$P_{k,0} = (\gamma_k - 1)\rho_{k,0}E_{k,0} - \gamma_k P_{k,\infty} = (\gamma_k - 1)\rho_0 e_{k,0} - \gamma_k P_{k,\infty}. \quad (43)$$

Using Eq. (43), the energy equation can be recast as a function of the leading-
 order pressure, P_0 , as follows:

$$\begin{aligned} A\alpha_{k,0} [\partial_t (P_k) + (\gamma_k - 1)\mathbf{u}_k \cdot \nabla P_k]_0 + (\gamma_k - 1)\alpha_{k,0} \nabla \cdot [A\mathbf{u}_k P_k]_0 + \\ \alpha_{k,0} (P_{k,0} + \gamma_k P_{k,\infty}) \nabla \cdot (\mathbf{u}_k A)_0 = \\ [\nabla \cdot (A\alpha_k \kappa_k \nabla (P_k))_0 + A\beta_{k,0} \nabla P_{k,0} \cdot \nabla \alpha_{k,0}]. \end{aligned} \quad (44)$$

315 From Eq. (41a), we infer that P_0 is spatially constant. Thus, Eq. (44) becomes

$$\frac{A}{\gamma(P_{k,0} + P_{k,\infty})} \frac{dP_0}{dt} = -\nabla \cdot (\mathbf{u}_k A)_0 \quad (45)$$

316 and, at steady state, we have

$$\nabla \cdot (\mathbf{u}_k A)_0 = 0. \quad (46)$$

317 That is, the leading-order of the product of velocity and cross section is divergence-
 318 free which corresponds to what is obtained when dealing with the multi-D Euler
 319 equations with variable area. Note that when assuming a constant cross sec-
 320 tion A , the usual divergence constraint, $\nabla \cdot \mathbf{u}_{k,0}$ is recovered. Also, Eq. (45) is
 321 slightly modified due to the use of the Stiffened Gas Equation of State in the
 322 asymptotic limit. However, the Ideal Gas Equation of State degenerates from
 323 the Stiffened Gas Equation of State by simply assuming $P_{k,\infty}$ which yields the
 324 usual leading-order single-phase energy equation with constant cross section:

$$\frac{1}{\gamma P_{k,0}} \frac{dP_0}{dt} = -\nabla \cdot \mathbf{u}_{k,0} \quad (47)$$

The same reasoning can be applied to the leading-order of the continuity equa-
 tion (Eq. (42b)) to show that the material derivative of the density variable is
 stabilized by well-scaled dissipative terms:

$$\left. \frac{D\alpha_k \rho_k}{Dt} \right|_0 := \partial_t (\alpha_k \rho)_0 + \mathbf{u}_{k,0} \cdot \nabla \cdot (\alpha_k \rho_k)_0 = \frac{1}{A} \nabla \cdot [\alpha_k A \kappa_k \nabla \rho + A \beta_k \rho_k \nabla \alpha_k]_0. \quad (48)$$

325 Therefore, we conclude that by setting the Reynolds and Péclet numbers to
 326 one, the incompressible fluid results are retrieved in the low-Mach limit when
 327 employing the compressible seven-equation model with viscous regularization
 328 and without relaxation terms.

329 4.3. Scaling of $Re_{k,\infty}$, $Pe_{k,\infty}^\kappa$ and $Pe_{k,\infty}^\beta$ for non-isentropic flows

Next, we consider the non-isentropic case. Recall that even subsonic flows
 can present shocks (for instance, a step initial condition in the pressure will trig-
 ger shock formation, independently of the Mach number). The non-dimensional
 form of the seven-equation model given in Eq. (38) provides some insight on
 the dominant terms as a function of the Mach number. This is particular ob-
 vious in the momentum equation, Eq. (38c), where the gradient of pressure is
 scaled by $1/M_{k,\infty}^2$. In the non-isentropic case, we no longer have $\frac{\nabla P_k}{M_{k,\infty}^2} = \nabla P_{k,2}$
 and therefore the pressure gradient term may need to be stabilized by some
 dissipative terms of the same scaling so as to prevent spurious oscillations from
 forming. By inspecting the dissipative terms presents in the momentum equa-
 tion, having a dissipative term that scales as $1/M_{k,\infty}^2$ leads to a total of eight

different options. Only three of them are investigated for brevity (note that the five other options can be ruled out by following the same reasoning as what is done next):

- (a) $\text{Re}_{k,\infty} = 1$, $\text{Pé}_{k,\infty}^\kappa = M_{k,\infty}^2$ and $\text{Pé}_{k,\infty}^\beta = 1$,
- (b) $\text{Re}_{k,\infty} = 1$, $\text{Pé}_{k,\infty}^\kappa = 1$ and $\text{Pé}_{k,\infty}^\beta = M_{k,\infty}^2$ or
- (c) $\text{Re}_{k,\infty} = M_{k,\infty}^2$, $\text{Pé}_{k,\infty}^\kappa = 1$ and $\text{Pé}_{k,\infty}^\beta = 1$.

Any of these choices will also affect the stabilization of the volume fraction, continuity and energy equations. For instance, using Péclet numbers equal to $M_{k,\infty}^2$ may effectively stabilize the volume fraction and continuity equation in the shock region but this may also add an excessive amount of dissipation for subsonic flows at the location of the contact wave. Such a behavior may not be suitable for accuracy purpose, making options (a) and (b) inappropriate. The same reasoning, left to the reader, can be carried out for the energy equation (Eq. (38d)) and results in the same conclusion. The remaining choice, option (c), has the proper scaling: in this case, only the dissipation terms involving $\nabla^{s,*} \mathbf{u}_k^*$ scale as $1/M_{k,\infty}^2$ since $\text{Re}_{k,\infty} = M_{k,\infty}^2$, leaving the regularization of the volume fraction and continuity equations unaffected because $\text{Pé}_{k,\infty}^\beta = \text{Pé}_{k,\infty}^\kappa = 1$.

4.4. An all-speed formulation of the viscosity coefficients

The study of the above limit cases yields two different possible scalings for the phasic Reynolds number: $\text{Re}_{k,\infty} = 1$ in the low-Mach limit and $\text{Re}_{k,\infty} = M_{k,\infty}^2$ for non-isentropic flows, whereas the phasic numerical Péclet numbers ($\text{Pé}_{k,\infty}^\kappa$ and $\text{Pé}_{k,\infty}^\beta$) always scales as one. In order to have a stabilization method valid for a wide range of Mach numbers, from very low-Mach to supersonic flows, these two scalings should be combined in a unique definition.

We begin with the normalization parameter $\text{norm}_{k,P}^\kappa$. Using the definition of the viscosity coefficients given in Eq. (30) and the scaling of Eq. (35), it can be shown that:

$$\kappa_{k,\infty} = \frac{\rho_{k,\infty} c_{k,\infty}^2 u_{k,\infty} L_{k,\infty}}{\text{norm}_{k,P,\infty}^\kappa} , \quad (49)$$

where $\text{norm}_{k,P,\infty}$ is the reference far-field quantity for the normalization parameter $\text{norm}_{k,P}$. Substituting Eq. (49) into Eq. (39) and recalling that the phasic numerical Péclet number scales as unity, we obtain:

$$\text{norm}_{k,P,\infty}^\kappa = \text{Pé}_{k,\infty} \rho_{k,\infty} c_{k,\infty}^2 = \rho_{k,\infty} c_{k,\infty}^2 . \quad (50)$$

Eq. (50) provides a proper normalization factor to define the κ_k viscosity coefficient. The derivation for $\text{norm}_{k,P}^\mu$ is similar and yields

$$\begin{aligned} \text{norm}_{k,P,\infty}^\mu &= \text{Re}_{k,\infty} \rho_{k,\infty} c_{k,\infty}^2 = \\ &\begin{cases} \rho_{k,\infty} \|u_{k,\infty}\|^2 & \text{for non-isentropic flows} \\ \rho_{k,\infty} c_{k,\infty}^2 & \text{for low-Mach flows} \end{cases} . \end{aligned} \quad (51)$$

354 A smooth function to transition between these two states is as follows:

$$\sigma(M_k) = \frac{\tanh(a_k(M_k - M_k^{\text{thresh}})) + |\tanh(a_k(M_k - M_k^{\text{thresh}}))|}{2}, \quad (52)$$

355 where M_k^{thresh} is a phasic threshold Mach number value beyond which the flow
 356 is no longer considered to be low-Mach (we use $M_k^{\text{thresh}} = 0.05$), M_k is the local
 357 Mach number, and the scalar a_k determines how rapidly the transition from
 358 $\text{norm}_{k,P,\infty}^\mu = \rho_k c_k^2$ to $\text{norm}_{k,P}^\mu = \rho_k \|\mathbf{u}_k\|^2$ occurs in the vicinity of M_k^{thresh} (we
 359 use $a_k = 3$). It is easy to verify that

$$\text{norm}_{k,P}^\mu = (1 - \sigma(M_k))\rho_k c_k^2 + \sigma(M_k)\rho_k \|\mathbf{u}_k\|^2 \quad (53)$$

360 satisfies Eq. (51).

361 It remains to determine the normalization parameter, $\text{norm}_{\alpha,k}^\beta$, for the vis-
 362 cosity coefficient β_k , by using the scaling of the Péclet number $\text{Pé}_{k,\infty}^\beta$ derived
 363 from the low-Mach asymptotic limit. Following the same reasoning as above, it
 364 yields:

$$\text{norm}_{k,\alpha,\infty}^\beta = 1, \quad (54)$$

365 where $\text{norm}_{k,\alpha,\infty}$ is the reference far-field quantity for the normalization pa-
 366 rameter $\text{norm}_{\alpha,k}$ used in the definition of the viscosity coefficient β_k (Eq. (31)).
 367 The normalization parameter scales as one. Then, it is chosen to use the same
 368 scaling as for Burger's equation [10] e.g.

$$\text{norm}_{k,\alpha}^\beta = \|\eta(\alpha_k) - \bar{\eta}(\alpha_k)\|_\infty, \quad (55)$$

369 where $\bar{\eta}$ is the average value of the entropy η over the entire computational
 370 domain.

371 At this point of the paper, we have derived a viscous regularization for the
 372 seven-equation model consistent with the entropy minimum principle, and de-
 373 fined viscosity coefficients for all-Mach flows. After describing the discretization
 374 scheme used (Section 5), 1-D numerical tests are performed in order to demon-
 375 strate the accuracy of our numerical method in Section 6.

376 5. Discretizations and Solution Techniques

377 In this section, we briefly describe the spatial and temporal discretizations
 378 and the solution techniques used to solve the system of equations Eq. (10). For
 379 conciseness, we re-write the system of equations in the following form:

$$\partial_t \mathbf{U}_k + \nabla \cdot \mathbf{F}_k(\mathbf{U}_k) = \mathbf{R}_k(\mathbf{U}_k) + \mathbf{N}_k(\mathbf{U}_k) + \nabla \cdot \mathbf{D}_k(\mathbf{U}_k) \nabla \mathbf{U}_k \quad (56)$$

380 where $\mathbf{U}_k = [(\alpha A)_k, (\alpha \rho A)_k, (\alpha \rho \mathbf{u} A)_k, (\alpha \rho E A)_k]^T$ is the solution vector, $\mathbf{F}_k(\mathbf{U}_k)$
 381 denotes the inviscid flux, $\nabla \cdot \mathbf{D}_k(\mathbf{U}_k) \nabla \mathbf{U}_k$ is the dissipative flux and $\mathbf{N}_k(\mathbf{U}_k)$
 382 and $\mathbf{R}_k(\mathbf{U}_k)$ contain the non-conservative and relaxation terms, respectively.

$$\mathbf{F} \equiv \begin{bmatrix} 0 \\ (\alpha \rho u A)_k \\ [\alpha (\rho u^2 + P) A]_k \\ [\alpha u (\rho E + P) A]_k \end{bmatrix}, \mathbf{N} \equiv \begin{bmatrix} -A \mathbf{u}_{int} \cdot \nabla \alpha_k \\ 0 \\ \alpha_k P_k \nabla A + P_{int} A \nabla \alpha_k \\ P_{int} A \mathbf{u}_{int} \cdot \nabla \alpha_k \end{bmatrix}$$

383

$$\text{and } \mathbf{R} \equiv \begin{bmatrix} A\mu_P (P_k - P_j) \\ 0 \\ A\lambda_u (\mathbf{u}_j - \mathbf{u}_k) \\ -\bar{P}_{int} A\mu_P (P_k - P_j) + \bar{u}_{int} A\lambda_u (\mathbf{u}_j - \mathbf{u}_k) \end{bmatrix}.$$

384 *5.1. Spatial and Temporal Discretizations*

385 The system of equations given in Eq. (56) is discretized using a continuous
 386 Galerkin finite element method and temporal integrators available through the
 387 MOOSE multiphysics framework [19].

388 *5.1.1. Continuous Finite Elements*

In order to apply the continuous finite element method, Eq. (56) is multiplied by a test function $\mathbf{W}(\mathbf{r})$, integrated by parts and each integral is decomposed into a sum of integrals over each element K of the discrete mesh Ω . The following weak form is obtained:

$$\begin{aligned} \sum_K \int_K \partial_t \mathbf{U} \mathbf{W} - \sum_K \int_K \mathbf{F}(\mathbf{U}) \cdot \nabla \mathbf{W} + \int_{\partial\Omega} \mathbf{F}(\mathbf{U}) \cdot \mathbf{n} \mathbf{W} - \sum_K \int_K (\mathbf{N}(\mathbf{U}) + \mathbf{R}(\mathbf{U})) \mathbf{W} \\ + \sum_K \int_K D(\mathbf{U}) \nabla \mathbf{U} \cdot \nabla \mathbf{W} - \int_{\partial\Omega} D(\mathbf{U}) \nabla \mathbf{U} \cdot \mathbf{n} \mathbf{W} = 0. \end{aligned} \quad (57)$$

389 The integrals over the elements K are evaluated using a numerical quadrature.
 390 The MOOSE framework provides a wide range of test functions and quadrature
 391 rules. Linear Lagrange polynomials are employed as test functions in the re-
 392 sults section. Second-order spatial convergence will be demonstrated for smooth
 393 solutions.

394 *5.1.2. Temporal integration*

395 The MOOSE framework offers both first- and second-order explicit and im-
 396 plicit temporal integrators. In all of the numerical examples presented in Sec-
 397 tion 6, the temporal derivative will be evaluated using the second-order, back-
 398 ward difference temporal integrator BDF2. By considering three consecutive
 399 solutions, \mathbf{U}^{n-1} , \mathbf{U}^n and \mathbf{U}^{n+1} , at times t^{n-1} , t^n and t^{n+1} , respectively, BDF2
 400 can be expressed as:

$$\int_K \partial_t \mathbf{U} \mathbf{W} = \int_K (\omega_0 \mathbf{U}^{n+1} + \omega_1 \mathbf{U}^n + \omega_2 \mathbf{U}^{n-1}) \mathbf{W}, \quad (58)$$

with

$$\omega_0 = \frac{2\Delta t^{n+1} + \Delta t^n}{\Delta t^{n+1} (\Delta t^{n+1} + \Delta t^n)}, \quad \omega_1 = -\frac{\Delta t^{n+1} + \Delta t^n}{\Delta t^{n+1} \Delta t^n},$$

$$\text{and } \omega_2 = \frac{\Delta t^{n+1}}{\Delta t^n (\Delta t^{n+1} + \Delta t^n)}$$

401 where $\Delta t^n = t^n - t^{n-1}$ and $\Delta t^{n+1} = t^{n+1} - t^n$.

402 5.2. Boundary conditions

403 Boundary conditions for the seven-equation model are challenging because
 404 of the wave-dominated nature of the equations but also because of the non-
 405 conservative form of the volume fraction equation. The boundary condition for
 406 the volume fraction equation (Eq. (1a)) is treated independently of the other
 407 equations (continuity, momentum and energy for each phase) for two reasons:
 408 (i) it is a simple advection equation with the real eigenvalue \mathbf{u}_{int} , and (ii),
 409 the hyperbolic flux, $\mathbf{u}_{int} \cdot \nabla \alpha_k$, is not integrated by part since not under a
 410 conservative form. The sign of the dot product between the eigenvalue and
 411 the outward normal to the boundary, $\mathbf{u}_{int} \cdot \mathbf{n}$, determines the nature of the
 412 boundary: negative for an inlet and positive for an outlet. For the later case,
 413 the physical information exits the computational domain and does not require
 414 any particular treatment. In the former case, the physical information enters
 415 the computational domain which requires to specify a value for the volume
 416 fraction. Since there is no flux at the boundary coming from the integration by
 417 part of the hyperbolic flux, the boundary value is imposed by using a Dirichlet
 418 boundary condition in the volume fraction equation. Our implementation of
 419 the boundary conditions for the continuity, momentum and energy equations,
 420 is inspired by the method described in [1] and was adapted for a time implicit
 421 solver [6]. The boundary type is identified from the study of the sign of the
 422 eigenvalues that depends on the Mach number. The numerical results presented
 423 in Section 6 were all obtained by using subsonic stagnation and static pressure
 424 boundary conditions for the inlet and outlet, respectively. The boundary flux is
 425 computed from the supplied variables at the boundary and also by iterating on a
 426 given number of variables (depending on the sign of the eigenvalues) though the
 427 implicit solver to transmit information from inside the computational domain
 428 toward the boundary.

429 The artificial diffusion coefficient $\mathbf{D}(\mathbf{U})$ is set to zero at the boundary of the
 430 computational domain so that the boundary term $\int_{\partial\Omega} \mathbf{D}(\mathbf{U}) \nabla \mathbf{U} \cdot \mathbf{n} \mathbf{W}$ stemming
 431 from the integration by parts of the artificial dissipative terms in Eq. (57) is
 432 ignored.

433 5.3. Solver

434 A Jacobian-free-Newton-Krylov (JFNK) method is used to solve for the so-
 435 lution at the end of each time step. An approximate Jacobian matrix of the
 436 discretized equations was derived and implemented. Obtaining the matrix en-
 437 tries requires that the partial derivatives of pressure with respect to the conser-
 438 vative variables be known (this is relatively simple for the stiffened and ideal
 439 gas equations of state but may be more complex for general equations of state).
 440 The contributions of the artificial dissipative terms to the Jacobian matrix are
 441 approximated by lagging the viscosity coefficients (computing them with the
 442 previous solution). For instance, this is shown in Eq. (59) for the dissipative
 443 terms present in the continuity equation:

$$\frac{\partial}{\partial \mathbf{U}} (\kappa \nabla \rho \cdot \nabla W) \simeq \kappa \nabla \cdot \frac{\partial \rho}{\partial \mathbf{U}} \nabla W, \quad (59)$$

where \mathbf{U} denotes any of the conservative variables and W denotes the component of \mathbf{W} associated with the continuity equation. In the above, we have neglected $\frac{\partial \kappa}{\partial \mathbf{U}}$.

6. 1-D numerical results

- simple advection problem
- shock tube with two independent fluids: exact solution and could do convergence test for this particular test
- shock tube with infinite relaxation coefficients
- 1-D nozzle with two independent fluids
- 1-D nozzle with infinite relaxation coefficients
- 1-D nozzle with infinite relaxation coefficients, mass and heat transfer

502 **Appendix A Entropy equation for the multi-D seven equation model**
 503 **without viscous regularization**

This appendix provides the steps that lead to the derivation of the phasic entropy equation of the seven-equation model [1]. For the purpose of this appendix, two phases are considered and denoted by the indexes j and k . In the seven-equation model, each phase obeys to the following set of equations (Eq. (60)):

$$\partial_t (\alpha_k A) + A \mathbf{u}_{int} \cdot \nabla \alpha_k = A \mu_P (P_k - P_j) \quad (60a)$$

$$\partial_t (\alpha_k \rho_k A) + \nabla \cdot (\alpha_k \rho_k \mathbf{u}_k A) = 0 \quad (60b)$$

$$\begin{aligned} \partial_t (\alpha_k \rho_k \mathbf{u}_k A) + \nabla \cdot [\alpha_k A (\rho_k \mathbf{u}_k \otimes \mathbf{u}_k + P_k \mathbb{I})] = \\ \alpha_k P_k \nabla A + P_{int} A \nabla \alpha_k + A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) \end{aligned} \quad (60c)$$

$$\begin{aligned} \partial_t (\alpha_k \rho_k E_k A) + \nabla \cdot [\alpha_k A \mathbf{u}_k (\rho_k E_k + P_k)] = \\ P_{int} A \mathbf{u}_{int} \cdot \nabla \alpha_k - \mu_P \bar{P}_{int} (P_k - P_j) + \bar{\mathbf{u}}_{int} A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) \end{aligned} \quad (60d)$$

504 where ρ_k , \mathbf{u}_k , E_k and P_k are the density, the velocity, the specific total energy
 505 and the pressure of phase k , respectively. The pressure and velocity relaxation
 506 parameters are denoted by μ_P and λ_u , respectively. The variables with subscript
 507 $_{int}$ correspond to the interfacial variables and a definition is given in Eq. (61).
 508 The cross section A is only function of space: $\partial_t A = 0$.

$$\left\{ \begin{array}{l} P_{int} = \bar{P}_{int} - \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} \frac{Z_k Z_j}{Z_k + Z_j} (\mathbf{u}_k - \mathbf{u}_j) \\ \bar{P}_{int} = \frac{Z_k P_j + Z_j P_k}{Z_k + Z_j} \\ \mathbf{u}_{int} = \bar{\mathbf{u}}_{int} - \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} \frac{P_k - P_j}{Z_k + Z_j} \\ \bar{\mathbf{u}}_{int} = \frac{Z_k \mathbf{u}_k + Z_j \mathbf{u}_j}{Z_k + Z_j} \end{array} \right. \quad (61)$$

509 where $Z_k = \rho_k c_k$ and $Z_j = \rho_j c_j$ are the impedance of phases k and j , respec-
 510 tively. The speed of sound is denoted by the symbol c . The function $sgn(x)$
 511 returns the sign of the variable x .

512 The first step consists of rearranging the equations given in Eq. (61) using the
 513 primitive variables $(\alpha_k, \rho_k, \mathbf{u}_k, e_k)$, where e_k is the specific internal energy of
 514 k^{th} phase. We introduce the material derivative $\frac{D(\cdot)}{Dt} = \partial_t(\cdot) + \mathbf{u}_k \cdot \nabla(\cdot)$ for
 515 simplicity.

516 The continuity equation is modified as follows:

$$\alpha_k A \frac{D\rho_k}{Dt} + \rho_k A \mu_P (P_k - P_j) + \rho_k A (\mathbf{u}_k - \mathbf{u}_{int}) \cdot \nabla \alpha_k + \rho_k \alpha_k \nabla \cdot (A \mathbf{u}_k) = 0 \quad (62)$$

517 The momentum and continuity equations are combined to yield the velocity
518 equation:

$$\alpha_k \rho_k A \frac{D\mathbf{u}_k}{Dt} + \nabla \cdot (\alpha_k A P_k) = \alpha_k P_k \nabla A + P_{int} A \nabla \alpha_k + A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) \quad (63)$$

The internal energy is obtained by subtracting the total energy from the kinetic equation defined as \mathbf{u}_k . Eq. (63):

$$\begin{aligned} \alpha_k \rho_k A \frac{De_k}{Dt} + \nabla \cdot (\alpha_k \mathbf{u}_k A P_k) - \mathbf{u}_k \cdot \nabla (\alpha_k A P_k) &= P_{int} A (\mathbf{u}_{int} - \mathbf{u}_k) \cdot \nabla \alpha_k \\ &\quad - \alpha_k P_k \mathbf{u}_k \cdot \nabla A - \bar{P}_{int} A \mu_P (P_k - P_j) + A \lambda_u (\mathbf{u}_j - \mathbf{u}_k) \cdot (\bar{\mathbf{u}}_{int} - \mathbf{u}_k) \end{aligned} \quad (64)$$

519 In the next step, we assume the existence of a phase wise entropy s_k function
520 of density ρ_k and internal energy e_k . Using the chain rule,

$$\frac{Ds_k}{Dt} = (s_\rho)_k \frac{D\rho_k}{Dt} + (s_e)_k \frac{De_k}{Dt}, \quad (65)$$

521 along with the internal energy (Eq. (64)) and the continuity equations (Eq. (62)),
522 the following entropy equation is obtained:

$$\begin{aligned} \alpha_k \rho_k A \frac{Ds_k}{Dt} + A \underbrace{(P_k (s_e)_k + \rho_k^2 (s_\rho)_k) \mathbf{u}_k \cdot \nabla \alpha_k + \alpha_k (P_k (s_e)_k + \rho_k^2 (s_\rho)_k) \mathbf{u}_k \cdot \nabla A}_{(a)} &= \\ (s_e)_k P_{int} A [(\mathbf{u}_{int} - \mathbf{u}_k) \cdot \nabla \alpha_k - \bar{P}_{int} A \mu_P (P_k - P_j) + A \lambda_u (\bar{\mathbf{u}}_{int} - \mathbf{u}_k) \cdot (\mathbf{u}_j - \mathbf{u}_k)] &- \\ \rho_k^2 (s_\rho)_k [\mu_P A (P_k - P_j) + A (\mathbf{u}_k - \mathbf{u}_{int}) \cdot \nabla \alpha_k] &\quad (66) \end{aligned}$$

523 where $(s_e)_k$ and $(s_\rho)_k$ denote the partial derivatives of the entropy s_k with
524 respect to the internal energy e_k and the density ρ_k , respectively. The second
525 term, (a), in the left hand side of Eq. (66) can be set to zero by assuming the
526 following relation between the partial derivatives of the entropy s_k :

$$P_k (s_e)_k + \rho_k^2 (s_\rho)_k = 0. \quad (67)$$

527 The above equation is equivalent to the application of the second thermody-
528 namic law when assuming reversibility:

$$T_k ds_k = de_k - \frac{P_k}{\rho_k^2} d\rho_k \text{ with } (s_e)_k = \frac{1}{T_k} \text{ and } (s_\rho)_k = -\frac{P_k}{\rho_k^2} (s_e)_k \quad (68)$$

529 Thus, equation Eq. (66) can be rearranged using the relation $(s_\rho)_k = -\frac{P_k}{\rho_k^2} (s_e)_k$:

$$\begin{aligned} ((s_e)_k)^{-1} \alpha_k \rho_k \frac{Ds}{Dt} &= \underbrace{[P_{int} (\mathbf{u}_{int} - \mathbf{u}_k) + P_k (\mathbf{u}_k - \mathbf{u}_{int})] \cdot \nabla \alpha_k}_{(b)} + \\ &\quad \underbrace{\mu_P (P_k - P_j) (P_k - \bar{P}_{int})}_{(c)} + \underbrace{\lambda_u (\mathbf{u}_j - \mathbf{u}_k) \cdot (\bar{\mathbf{u}}_{int} - \mathbf{u}_k)}_{(d)} \end{aligned} \quad (69)$$

530 The right hand side of equation Eq. (69) is split into three terms (b), (c) and (d)
 531 that will be dealt with separately. The terms (c) and (d) can be easily recast
 532 by using the definitions of $\bar{\mathbf{u}}_{int}$ and \bar{P}_{int} given in equation Eq. (61):

$$\begin{aligned}\mu_P(P_k - P_j)(P_k - \bar{P}_{int}) &= \mu_P \frac{Z_k}{Z_k + Z_j} (P_j - P_k)^2 \\ \lambda_u(\mathbf{u}_j - \mathbf{u}_k) \cdot (\bar{\mathbf{u}}_{int} - \mathbf{u}_k) &= \lambda_u \frac{Z_j}{Z_k + Z_j} (\mathbf{u}_j - \mathbf{u}_k)^2\end{aligned}\quad (70)$$

533 By definition, μ_P , λ_u and Z_k are all positive. Thus, the above terms (c) and
 534 (d) are unconditionally positive.
 535 It remains to look at the last term (b). Once again, by using the definition of
 536 \bar{P}_{int} and \mathbf{u}_{int} , and the following relations:

$$\begin{aligned}\mathbf{u}_{int} - \mathbf{u}_k &= \frac{Z_j}{Z_k + Z_j} (\mathbf{u}_j - \mathbf{u}_k) - \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} \frac{P_k - P_j}{Z_k + Z_j} \\ P_{int} - P_k &= \frac{Z_k}{Z_k + Z_j} (P_j - P_k) - \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} \frac{Z_k Z_j}{Z_k + Z_j} (\mathbf{u}_k - \mathbf{u}_j),\end{aligned}$$

537 term (b) becomes:

$$\begin{aligned}[P_{int}(\mathbf{u}_{int} - \mathbf{u}_k) + P_k(\mathbf{u}_k - \mathbf{u}_{int})] \cdot \nabla \alpha_k &= (P_{int} - P_k)(\mathbf{u}_{int} - \mathbf{u}_k) \cdot \nabla \alpha_k = \\ &= \frac{Z_k}{(Z_k + Z_j)^2} \nabla \alpha_k \cdot \left[Z_j(\mathbf{u}_j - \mathbf{u}_k)(P_j - P_k) + \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} Z_j^2 (\mathbf{u}_j - \mathbf{u}_k)^2 + \right. \\ &\quad \left. \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} (P_k - P_j)^2 + \frac{\nabla \alpha_k \cdot \nabla \alpha_k}{\|\nabla \alpha_k\|^2} (P_k - P_j) Z_j (\mathbf{u}_k - \mathbf{u}_j) \right]\end{aligned}\quad (71)$$

The above equation is factorized by $\|\nabla \alpha_k\|$ and then recast under a quadratic form using $\frac{\nabla \alpha_k \cdot \nabla \alpha_k}{\|\nabla \alpha_k\|^2} = 1$. This yields:

$$\begin{aligned}[(\mathbf{u}_{int} - \mathbf{u}_k)P_{int} + (\mathbf{u}_k - \mathbf{u}_{int})P_k] \nabla \alpha_k &= \\ \|\nabla \alpha_k\| \frac{Z_k}{(Z_k + Z_j)^2} \left[Z_j(\mathbf{u}_j - \mathbf{u}_k) + \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} (P_k - P_j) \right]^2\end{aligned}\quad (72)$$

Thus, using Eq. (69), Eq. (70), Eq. (71) and Eq. (72), the entropy equation obtained in [1] holds and is recalled here for convenience:

$$\begin{aligned}(s_e)_k^{-1} \alpha_k \rho_k A \frac{Ds_k}{Dt} &= \mu_P \frac{Z_k}{Z_k + Z_j} (P_j - P_k)^2 + \lambda_u \frac{Z_j}{Z_k + Z_j} (\mathbf{u}_j - \mathbf{u}_k)^2 \\ &\quad + \frac{Z_k}{(Z_k + Z_j)^2} \left[Z_j(\mathbf{u}_j - \mathbf{u}_k) + \frac{\nabla \alpha_k}{\|\nabla \alpha_k\|} (P_k - P_j) \right]^2.\end{aligned}$$

538 Appendix B Compatibility of the viscous regularization for the seven- 539 equation two-phase model with the generalized Harten 540 entropies

541 We investigate in this appendix whether the viscous regularization of the
 542 seven-equation two-phase model derived in Section 3 is compatible with some

or all generalized entropy identified in Harten et al. [12]. Considering the single-phase Euler equations, Harten et al. [12] demonstrated that a function $\rho\mathcal{H}(s)$ is called a generalized entropy and strictly concave if \mathcal{H} is twice differential and

$$\mathcal{H}'(s) \geq 0, \quad \mathcal{H}'(s)c_p^{-1} - \mathcal{H}'' \geq 0, \quad \forall (\rho, e) \in \mathbb{R}_+^2, \quad (73)$$

where $c_p(\rho, e) = T\partial_T s(\rho, e)$ is the specific heat at constant pressure (T is a function of e and ρ through the equation of state). Because the seven-equation two-phase model was initially derived by assuming that each phase obeys the single-phase Euler equation, we want to investigate whether the above property still holds when considering the seven-equation model with viscous regularization. To do so, we consider a phasic generalized entropy, $\mathcal{H}_k(s_k)$ and a phasic specific heat at constant pressure, $c_{p,k}(\rho_k, e_k) = T_k\partial_{T_k} s_k(\rho_k, T_k)$ characterized by Eq. (73). The objective is to find an entropy inequality verified by $\rho_k\mathcal{H}_k(s_k)$.

We start from the entropy inequality verified by s_k ,

$$\begin{aligned} \alpha_k \rho_k A \frac{Ds_k}{Dt} &= \mathbf{f}_k \cdot \nabla s_k + \nabla \cdot (\alpha_k A \rho_k \kappa_k \nabla s_k) \\ &\quad - \alpha_k \rho_k A \kappa_k \mathbf{Q}_k + (s_e)_k \alpha_k A \rho_k \mu_k \nabla^s \mathbf{u}_k : \nabla \mathbf{u}_k. \end{aligned} \quad (74)$$

Eq. (74) is multiplied by $\mathcal{H}'_k(s_k)$ to yield:

$$\begin{aligned} \alpha_k \rho_k A \frac{D\mathcal{H}_k(s_k)}{Dt} &= \nabla \cdot (\alpha_k A \rho_k \kappa_k \nabla \mathcal{H}_k(s_k)) - \mathcal{H}''_k(s_k) \alpha_k A \kappa_k \rho_k \|\nabla s_k\|^2 + \\ &\quad \mathcal{H}'_k(s_k) \mathbf{f}_k \cdot \nabla s_k - \mathcal{H}'_k(s_k) \alpha_k \rho_k A \kappa_k \mathbf{Q}_k + \\ &\quad \mathcal{H}'_k(s_k) (s_e)_k \alpha_k A \rho_k \mu_k \nabla^s \mathbf{u}_k : \nabla \mathbf{u}_k. \end{aligned} \quad (75)$$

Let us now multiply the continuity equation of phase k by $\mathcal{H}_k(s_k)$ and add the result to the above equation to obtain:

$$\begin{aligned} &\partial_t (\alpha_k \rho_k A \mathcal{H}_k(s_k)) + \nabla \cdot (\alpha_k \rho_k \mathbf{u}_k A \mathcal{H}_k(s_k)) - \\ &\nabla \cdot [\alpha_k A \rho_k \kappa_k \nabla \mathcal{H}_k(s_k) + \alpha_k A \kappa_k \mathcal{H}_k(s_k) \nabla \rho_k + A \kappa_k \rho_k \mathcal{H}_k(s_k) \nabla \alpha_k] = \\ &\underbrace{-\mathcal{H}''_k(s_k) \alpha_k A \kappa_k \rho_k \|\nabla s_k\|^2 - \mathcal{H}'_k(s_k) \alpha_k A \kappa_k \rho_k \mathbf{Q}_k}_{\mathbb{T}_0} + \\ &\underbrace{\mathcal{H}'_k(s_k) (s_e)_k \alpha_k A \rho_k \mu_k \nabla^s \mathbf{u}_k : \nabla \mathbf{u}_k}_{\mathbb{T}_1}. \end{aligned} \quad (76)$$

As in Section 3, the left-hand side of Eq. (76) is split into two residuals denoted by \mathbb{T}_0 and \mathbb{T}_1 in order to study the sign of each of them. We start by studying the sign of \mathbb{T}_1 that is positive since it is assumed that $\mathcal{H}'_k(s_k) \geq 0$. We now investigate the sign of \mathbb{T}_0 . Using Eq. (73), it is obtained:

$$-\mathbb{T}_0 \leq \mathcal{H}'_k(s_k) \alpha_k A \kappa_k \rho_k \left(c_{p,k}^{-1} \|\nabla s_k\|^2 + \mathbf{Q}_k \right). \quad (77)$$

The right-hand side of Eq. (77) is a quadratic form that was already defined in Appendix 5 of [5] and recast under the matricial form $X_k^t \mathbb{S} X_k$ where \mathbb{S} is a

2×2 matrix and the vector X_k is defined in Section 3. In [5], the matrix \mathbb{S} is proved to be negative semi-definite which allows us to conclude that $-\mathbb{T}_0$ is of the same sign using Eq. (77). Then, knowing the sign of the two residuals \mathbb{T}_0 and \mathbb{T}_1 , we conclude that:

$$\begin{aligned} & \partial_t (\alpha_k \rho_k A \mathcal{H}_k(s_k)) + \nabla \cdot (\alpha_k \rho_k \mathbf{u}_k A \mathcal{H}_k(s_k)) - \\ & \nabla \cdot [\alpha_k A \rho_k \kappa_k \nabla \mathcal{H}_k(s_k) + \alpha_k A \kappa_k \mathcal{H}_k(s_k) \nabla \rho_k + A \kappa_k \rho_k \mathcal{H}_k(s_k) \nabla \alpha_k] \geq 0 , \end{aligned}$$

558 which allows us to conclude that an entropy inequality is satisfied for all gen-
 559 eralized entropies $\rho_k \mathcal{H}_k(s_k)$ when using the viscous regularization derived in
 560 Section 3 for the seven-equation two-phase model. Note that the above inequal-
 561 ity holds for the total entropy of the system when summing over the phases.
